Case status: Completed

Case notes:

No presenting complaints-routine screening

The report:

309742 KW/lb

Four digitalized radiographic images containing projections of the pelvis and elbows were submitted for evaluation. The radiographs are dated 06/24/15.

Radiographic Findings:

Both femoral heads are located in their respective acetabula and are congruous with the acetabular rims.

Greater than 50% of the femoral heads are located medial to the dorsal acetabular rims.

No osteophyte formation is present on the femoral necks or acetabula.

Alignment of the patellae with the femurs is normal.

Muscle volume in both hind legs is within normal limits.

The anconeal process of both ulnae and proximocranial aspect of both radii are smooth with no evidence of osteophyte formation.

No sclerosis is associated with the ulnar notches.

Both medial coronoid processes appear smooth in contour and a fragment associated with the medial coronoid processes is not identified.

Radiologic Diagnosis: Normal pelvis and elbows.

Comments: Radiographic changes to suggest elbow or hip dysplasia are not present. Based on the OFA scheme evaluating hips, the hips would be rated as excellent in conformation. Radiographs obtained at two years of age will need to be evaluated to completely exclude elbow and hip dysplasia.
